

I Am The Firm! Eponymous Firms and Rose-Coloured Forecasts

Doron Kliger,* Yevgeny Mugerma,** and Ruth Rooz***

December 2020

Abstract

We invoke the famous Louis XIV quote “L'État, c'est moi,” applying it to the corporate world, and introduce the novel idea that a self-serving bias, which we define as “I Am The Firm,” is infused within the culture of certain companies. We hypothesize that the owners of eponymous firms – firms that bear the names of their owners – experience enhanced self-identification with their firms, and thus tend to inject their own subjective beliefs and desires into the realistic objective prospects of the firms. The “I am the firm” effect is a form of a self-serving bias, which arises from the blurring of boundaries between the owner and the corporate eponymy entity that carries the same name. Employing a unique corporate setting in Israel, we demonstrate that eponymous firms disclose unduly optimistic biased forecasts relative to their non-eponymous counterparts, which cannot be validated or justified by rational explanations solely. The obfuscation of the boundaries in eponymous firms between subjective illusory desires and objective realistic truths is revelatory and has far-reaching implications in various aspects of corporate decisions.

Keywords: management forecasts; cash flow forecasts; behavioral biases; eponymous firms; family ownership.

We are grateful to Xia Chen, Beni Lauterbach, Shai Levi, Roni Michaely, Ori Putterman, Benjamin Segal, Eyal Winter, and Yishay Yafeh for valuable comments and suggestions. We gratefully acknowledge financial support from the Raya Strauss Center for Family Business Research at the Coller School of Management, the Tel Aviv University.

1. Introduction

Every important corporate decision can be said to involve a rearranging of boundaries. Where precisely does the wishful desire of management end and the best interest of the corporate entity begin? In this paper, we examine whether a blurring of boundaries between the firm and its management leads to an "I Am The Firm" (ITF) self-serving belief that influences future business forecasts.¹ Prior literature suggests that managers are not immune to optimism (Kahneman and Lovallo, 1993) and are likely to fall victim to wishful thinking (Koonce et al., 2011) when making predictions; yet, testing the existence of this optimistic bias or wishful thinking in actual management forecast predictions is quite challenging. Disentangling behavioral biases from other incentives to bias forecasts upward is not obvious. In fact, the literature finds evidence that management has incentives to bias forecasts upward in order to reduce the probability of dismissal, bankruptcy, acquisition, or hostile takeover (Frost, 1997); Rogers & Stocken, 2005). In other words, the behavioral aspect of optimistic bias in management forecasts is tainted with rational incentives to provide these upwardly biased forecasts. To study behavioral bias in forecast predictions of management, we develop a parsimony analytical model. We test empirically the hypothesis derived from the model utilizing a unique setting from Israel where firms are required, in certain circumstances, to disclose mandatory cash flow forecasts, where the latitude over the numbers included in the forecasts is relatively limited, as will be further explained below. Furthermore, we disentangle the behavioral "I Am The Firm" aspect in optimistic bias by classifying our data into a unique firm characteristic with an enhanced potential for behavioral features in the form of "eponymous firms," i.e., firms that carry the name of the owner.

On February 23, 2010, Akio Toyoda, the President of Toyota Motor Corporation and its founder's grandson, declared to the U.S. Congress: "*My name is on every car. You have my personal commitment that Toyota will work vigorously and unceasingly to restore the trust of our customers.*"² When Mr. Toyoda attempted to assuage Congress about safety issues that were discovered in Toyota's cars, he specifically invoked the

¹ From the psychological perspective, this evidence may include: i) over-confidence; ii) over-optimism; iii) cognitive dissonance; and iv) self-serving belief bias. The latter seems to play a role in our setting, as managers in family firms may have a greater tendency to interpret ambiguous evidence as supporting a desirable conclusion. The body of the psychological literature in the realm of self-serving bias is vast. See, for example, Campbell and Sedikides (1999), Campbell et al., (2000), Pal (2007).

²Bennedsen, M., Mehrotra, V., Shim, J., & Wiwattanakantang, Y. (2020). Dynastic Control without Ownership: Evidence from Post-war Japan. *European Corporate Governance Institute–Finance Working Paper*, (705).

name of the company – *his own name* – to provide comfort to the public. As this example suggests, when a firm carries an invested person's name, more is at stake than mere finances – a deeply personal and psychological element comes into play. This unique firm characteristic serves the shareholders for better, as Mr. Toyoda suggested, but also for worse, as we identify and demonstrate an "I Am The Firm" bias in management forecasts.

We examine ITF bias in management forecasts by exploiting a unique regulatory setup that exists in Israel. In our setting, financially distressed firms with publicly traded bonds are required by the Israeli Security Authority (ISA, which is the Israeli equivalent of the SEC) to disclose cash flow forecasts in their periodic financial statements. The forecasts mandated by ISA have unique features that make it costly for firms to manipulate their numbers. First, management forecasts in other jurisdictions are voluntarily disclosed, raising concerns of selection bias, as well as bias in the timing and form of disclosure.³ In contrast, our setting offers specific forward-looking information in the form of cash flow forecasts that are *mandatorily* disclosed and are closely regulated. Second, firms are required by the ISA to include *detailed* cash inflows and outflows, and are prohibited from including cash flows if the likelihood of receiving such flows is not *feasible*, which differs from voluntary forecasts where firms have greater latitude over the numbers they include in their forecasts. The use of cash flows forecasts, relative to earnings forecasts or other quality measure forecasts, has an additional inherent advantage since cash flows are *less prone to earning manipulation* (Wasly & Wu, 2006; Dechow, 1994). Third, ISA vigorously *enforces* the disclosure requirements and penalizes firms that do not provide adequate cash flow forecasts disclosure. Moreover, firms are required to disclose in their subsequent periodic statements if the realization of the cash flow forecast *deviated* significantly. Finally, we find that the market penalizes firms that disclose unduly optimistic forecasts. These factors indicate that, unlike other management forecasts, in our setting, the ramifications would be costly in the event that a firm would bias its forecasts upward. On the other hand, distressed firms are not motivated to provide forecasts that are particularly conservative since that might precipitate the process of bankruptcy. Therefore, firms are facing two competing forces that direct them to predict the most accurate possible forecasts since, on the one hand, they are limited in their ability to

³ E.g. range, point or qualitative forms of disclosure.

upwardly bias the forecasts and, on the other hand, they are otherwise disincentivized from biasing forecasts downward.

In order to identify mandatory cash-flow forecasts in annual financial statements of listed companies, we utilize a web scraping tool and find 384 firm-year cash flow forecasts for the years spanning 2011 to 2018. We split our data into eponymous and non-eponymous firms, and assess whether eponymous firms are associated with significantly greater optimistic forecasts. Consistent with our hypothesis, we find that the likelihood of eponymous firms predicting optimistic forecasts is more than three times larger than of non-eponymous firms making such predictions. However, we do not find evidence that these over optimistic cash flow forecasts are associated with increased managerial effort.⁴ Such optimistic forecasts persist despite our finding that eponymous firms are penalized more than non-eponymous firms by the market for disclosing overly optimistic forecasts, per our testing via cumulative return around earning announcements. We examine other rational alternative explanations for optimistic forecasts in eponymous firms: first we test whether our results are driven by the number of shares held by the controlling family in eponymous firms relative to shares held by the largest block holder in non-eponymous firms; second, we test whether prior experience of firms in providing these cash flow forecasts, as well as deviation from prior forecasts, leads to more conservative predictions. We find that neither the number of shares held by the owning family nor their experience with prior deviation of forecasts can explain our results of unduly optimistic forecasts, which supports our hypothesis of self-serving bias of ITF in predictions of eponymous firms. Additionally, we extend our examination to a broader definition of family firms, which includes firms with two or more family members serving on the board of directors or as high-level executives (as defined in prior literature, for example: Anderson and Reeb, 2003; Villalonga and Amit, 2006; Weiss, 2014; Abudy and Shust, 2019). We find that our results attenuate when using a broader definition of family firms, which, consistent with our hypothesis, suggests that ITF effect is driven primarily by eponymous firms that are more prone to behavioral bias. Finally, we find that the number of family members in eponymous firms relative to other firms is not driving our results. Overall,

⁴ We test whether the change in the probability of default (which we use to proxy for managerial effort in financially distressed firms) is associated with managerial optimism. The tests for examining managerial effort as implemented by the literature (see for example: Hilary et al. 2016) are less adequate to our financially distressed firms' dataset.

we conclude that although eponymous firms have greater reputational concern (Belenzon, Chatterji and Daley, 2017) and are otherwise penalized for providing inordinately optimistic projections in our set-up, eponymous firms are tainted with ITF behavioral bias that elicits a blurring of boundaries between their self-desires and their firms' objective realistic truths, which motivates them to prognosticate unrealistic forecasts.

Our primary contribution is that we *identify a new "I Am The Firm" bias effect*. We believe that our research is at the vanguard of the study of behavioral biases in family-owned firms – by using actual forecast data,⁵ we contribute to the understanding of the influence of family ownership on corporate decision making in general, and forecast prediction in particular, from a behavioral point of view.

In addition, as a result of our study of a unique mandatory disclosure of management cash flow forecasts by family-owned firms vs. non-family-owned firms, we contribute to the understanding of essential accounting, financial and economic aspects of family businesses that have ramifications upon other estimations and forecasts provided by family firms. Through our research, which focuses on a particular construct of family ownership, we shed light on a singular sub-group of eponymous family firms that has distinctly intensified business characteristics (e.g., heightened reputational concerns) that have not been extensively studied by prior research.

The remainder of this paper is organized as follows. Section 2 reviews the related literature. Section 3 describes the institutional background. Section 4 provides a conceptual framework within which we develop an analytical model that establishes our hypotheses. Section 5 describes our sample, data, measures and descriptive statistics. Section 6 presents the research design and the empirical findings. Section 7 concludes the paper.

2. Literature

We focus on two main strands of literature to develop our hypothesis. The first strand deals with both rational and behavioral explanations for unrealistic optimism in management forecasts, with a focus on firms confronting financial distress. In the

⁵ An additional insight is that we employ *real* forecasts data to study a behavioral aspect. For example, Chen, Rennekamp and Zhou (2015) study management forecasts in a lab experiment setting.

second strand of literature, we focus on the characteristics of eponymous and family firms.

2.1 Unrealistic optimism

Prior literature exhibits rational incentives of firms in disclosing optimistic/upward biased forecasts. Frost (1997) suggests that distressed firms have incentives to provide encouraging news in order to reduce the probability of bankruptcy, acquisition, or hostile takeover. Rogers & Stocken (2005) hypothesize that firms in financial distress have incentives to disclose encouraging forecasts; yet, using US data, they find that the willingness of financially distressed firms to issue optimistic forecasts varies with the investors' ability to detect the misrepresentation. Kato et al. (2009) examine management forecasts in Japan, where forecasts are effectively mandated, as the Tokyo stock exchange strongly encourages firms to disclose sales and net income forecasts. The authors argue that since, *de facto*, most firms disclose those forecasts, they are effectively mandated; however, these Japanese firms have considerable latitude over the numbers they release. They find that forecasts are systematically upwardly biased, and conclude that managers tend to provide optimistic forecasts when forecasts are relatively unconstrained by legal or regulatory forces. Hilary et al. (2016) provides rational evidence for positive earnings management forecasts, that generates higher managerial effort that improves firm profitability and market value. In addition to the incentive explanation for optimistic forecasts, the literature provides behavioral explanations as well. Kahneman and Lovallo (1993) explain how overconfidence, illusion of control as well as the inside vs. outside views of problems by manager/individuals lead them to provide bold forecasts. Michaely and Womack (1999) indeed document optimistic bias by underwriter analysts forecasts that is explained, inter alia, by a genuinely believe that the firms they underwrite are better, hence supporting the inside view explanation. DellaVigna (2009) provides certain underlying behavioral reasons, such as the "projection bias" and the "law of small numbers," in explaining optimistic bias. Overall, the literature above suggests that regulated forecasts should attenuate the incentives and ability of firms to disclose upwardly biased forecasts. Yet, some behavioral aspect in management forecasts play an important role as well. In the next sub-section, we describe the literature on eponymous and family firms, a sub-group of firms in which, we claim, the behavioral aspect is more pronounced.

2.2 Eponymous and family firms' characteristics

Prior research in the realm of strategic has delved into the decisions of owners/entrepreneurs to designate their own names to their firms. Belenzon et al. (2017) suggest that attaching the owner's identity into the firm's name is a strategic decision and serves as an important signal. Belenzon et al. find that although eponymous firms are associated with greater performance, such firms are relatively uncommon (only 19% of firms in their European data); they conclude that reputational concerns are enhanced in eponymous firms, which is the main explanation for the less common phenomena of naming firms after the owners and founders. Eponymous firms are also studied in the context of family firms; Anderson et al. (2003) hypothesize that founding family firms have fewer agency conflicts between equity and debt claimants, and find that founding families have consistently lower cost of debt. Anderson et al. highlight the reputational concerns that are more pronounced in eponymous family firms. Building on the reputational concern of eponymous firms, together with lower agency conflicts and the independence of management's reward on financial outcomes, Minichilli et al. (2020) find that eponymous firms in Italy are associated with higher quality of financial reporting and lower cost of debt. Other researchers defining family firms in broader ways find similar results: Ali et al. (2007) determine that family firms have higher quality of disclosures, Martin et al. (2016) find that family firms practice less earnings management, Weiss (2014) observes less material weaknesses in internal controls of family firms, and Abudy and Shust (2019) find that family firms exhibit anti-sticky cost behavior. Overall, these findings indicate that eponymous firms, and family firms in general, have lower agency conflicts and greater reputation concern, and are therefore expected to disclose more accurate and less biased forecasts. On the other hand, Sageder et al. (2018) claim that families have personal attachments, and are more identified with, their firms, and tend to be more involved in its management. Such personal ties could motivate these family firms to imagine more optimistic outcomes.

3. Institutional Background

3.1 The Israeli Corporate Bond Market

The development of the Israeli corporate bond market expanded dramatically in the first decade of the 2000s, as the aggregate market cap of corporate bonds increased from \$6

billion in 2003 to \$73 billion in 2009 (Abudy and Wohl, 2018). Abudy and Wohl find that despite its relatively small size, the Israeli market is quite liquid, characterized by high trading volumes and low spreads relative to the US corporate bond market. One of the reasons for the development of the Israeli bond market was local regulatory changes that relaxed prior limitations on long-term corporate bond investing by long-term saving institutions. The significant increase in capital supply proliferated the offerings of corporate public bonds, causing firms to substantially increase their leverage ratios.

3.2 Mandatory Disclosure of Cash-Flow Forecasts

In 2008, in the midst of the global credit crisis, many companies encountered difficulties in repaying their debt to bond holders. As a response, ISA has required companies listed on the Tel-Aviv Stock exchange that have bonds held by the public and are facing financial distress to disclose cash flow forecasts for the upcoming two years in their periodic financial statements.⁶

The ISA mandatory disclosure requirement exemplifies one aspect of dealing with financial distress – transparency. It attempts to raise investors' attention to the risk of liquidity, or lack thereof, that the investee might be facing in repaying future upcoming debt payments at an early stage of financial distress. Specifically, ISA requires companies to disclose their cash flow forecasts in the event that the following two conditions are met:

1. Some of the company's traded bonds were held by the general public, i.e., by less savvy investors that lack access to more sophisticated channels of financial information. Firms whose traded bonds were held solely by institutions are excluded from the disclosure regulation.
2. The firm encountered financial distress identified by certain "warning signals," as reflected by intimations of adverse values of one or more financial figures, including equity deficit, negative working capital and ongoing negative cash flow from operations, or "emphasis of matter" in the auditors' report. According to an interview we conducted with a senior ISA officer, these warning signals were selected by reverse engineering, i.e., identifying early signs of firms that

⁶ See ISA Annual Report for 2008, http://www.isa.gov.il/download/isafile_4543.pdf.

subsequently went bankrupt or were subjected to a debt reorganization. We note that these financial warning signals are indeed also part of the O-Score model for predicting bankruptcy (Ohlson 1980).

Thus, it is clear that cash flow forecasts provide essential information with respect to firms that are in financial distress, and are a key factor in alleviating the "going concern" assumption (the assumption being that the firms are viable businesses that will meet their financial obligations) that is crucial to the preparation of financial statements.

3.3 The Costs of Disclosing Biased Cash-Flow Forecasts

The ISA's cash flow forecast disclosure regulation includes thorough requirements to incorporate detailed cash inflows and outflows. Firms are instructed to include cash flows only if the likelihood of receiving such flows is feasible, which differs from voluntary forecasts where firms have far greater latitude over the numbers they include in their forecasts. The use of cash flows forecasts, relative to earnings forecasts or other quality measure forecasts, has an inherent advantage, since cash flows are *less prone to earning manipulation* (Wasly & Wu, 2006; Dechow, 1994). Additionally, firms are required to disclose, in their subsequent periodic statements, if the realization of the cash flow forecast deviated significantly from their forecasts. Moreover, in 2010, in light of flaws that were detected by ISA inspections of firms' cash flow forecasts, ISA published a revised disclosure requirement that clarified and calibrated its prior mandate. For example, ISA elucidated that firms should disclose expected cash flows on a "solo" level (and not a consolidated level), and that firms may not include expected dividends from a subsidiary as cash inflows if such dividends are not feasible. ISA regulates and enforces the forecast requirement vigorously, as reflected by several precedents of ISA requiring firms to revise and resubmit the cash flow forecasts, and cases of ISA penalizing firms that failed to provide adequate forecasts.⁷ Moreover, as will be demonstrated below, the market penalizes firms that disclose unduly optimistic forecasts as well.

⁷ See, for example, http://www.isa.gov.il/%D7%97%D7%A7%D7%99%D7%A7%D7%94%20%D7%95%D7%90%D7%9B%D7%99%D7%A4%D7%94/Enforcement/Financial_sanctions/EITZUMIM/Documents/120717.pdf (a court case regarding an Israeli energy company being penalized by ISA for disclosing non-conservative cash-flow forecasts, in Hebrew).

In short, the cash flow forecasts constitute an essential component of information, generated and provided by the highest executive levels within the firm, and are rigorously enforced both by regulatory and market forces, all of which provide an ideal setting for our research project.

4 Conceptual Framework

In this Section, we develop a simple analytical model that establishes several hypotheses that will be tested empirically in the ensuing sections. We assume that the firm's owner maximizes her subjective utility (SU), composed of a psychological (self-esteem) factor (PF), and an economic factor (EF).

$$SU = PF + EF$$

To elaborate, the first component of the subjective utility model involves the firm owner's *current* feelings with respect to the firm, and the second component captures the firm's economic value, which depends on future realizations.

PF depends on the owner's degree of self-identification with the firm (SID), multiplied by the firm's currently perceived potential (PP):

$$PF = SID \cdot PP$$

EF depends on the owner's share in the firm (α), multiplied by the net present value of the firm (NPV):⁸

$$EF = \alpha \cdot NPV$$

Plugging the above into the owner's subjective utility function yields:

$$SU = SID \cdot PP + \alpha \cdot NPV$$

We turn now to the factors affecting the variables in the two utility components. SID is larger in case of eponymous ownership (EO). Further, SID is positively related to the number of family members serving in the firm (FM):⁹

⁸ For simplicity, we ignore here issues of capital structure, assuming an unleveraged firm. This is inconsequential to the model's hypotheses for the current research.

⁹ To ease notation, we treat all variables as continuous, even though EO, for example, is not continuous. Rather, EO is an indicator which equals one with respect to eponymous firms, and zero otherwise. This ease of notation is inconsequential with regard to our model's hypotheses.

$$\frac{\partial SID}{\partial X} > 0; X \in \{EO, FM\}$$

PP is increasing and concave in the value of the projected cashflow (PCF):

$$\frac{\partial PP}{\partial PCF} > 0, \quad \frac{\partial^2 PP}{\partial PCF^2} < 0$$

Increasing is straightforward: the higher (i.e., more optimistic) the PCF, the more self-serving it is. Concavity results from the fact that the higher the PCF, the less self-convincing is its validity (the owner may fool herself to some degree, but exaggerating makes the forecast less reliable, even to the self).

NPV is composed of the firm's discounted net cash flow from its activities (NPV_a), plus a negative component proportional to the damage due to misreporting the cash flow. That damage may be formulated as the probability of the to-be-realized cash flow to be larger than the realized cash flow reported in the forecast (Q), multiplied by the probability of sanctions given a violation ($PSANC$)¹⁰ and multiplied by the economic size of the sanction (Fine).¹¹¹² Thus, NPV is represented as:

$$NPV = NPV_a - Q(PCF) \cdot PSANC(PCF) \cdot Fine$$

Logically, the term ($Q \cdot PSANC$) is increasing in the value of the projected cashflow (PCF), i.e., the higher the PCF, the more likely it is to be inflated, and also the more likely it is that ISA would sanction the firm, i.e., $\frac{\partial Q}{\partial PCF} > 0$ and $\frac{\partial PSANC}{\partial PCF} > 0$. Therefore, we may concisely write that:

$$\frac{\partial(Q(PCF) \cdot PSANC(PCF))}{\partial PCF} > 0$$

Furthermore, we assume that ($Q \cdot PSANC$) is convex in PCF, mainly because ISA would be more likely to focus on punishing the extreme violators. Thus:

$$\frac{\partial^2(Q(PCF) \cdot PSANC(PCF))}{\partial PCF^2} > 0$$

¹⁰ A sanction could be imposed by the regulator and/or by the market, as will be discussed below.

¹¹ In an augmented model, we would formulate $PSANC$ and $Fine$ as functions of PCF ; here, for simplicity, they are kept constant.

¹² To maintain a parsimonious model here, we assume that $Fine$ is exogenous. Taking $Fine$ as endogenous is straightforward and retains our testable hypotheses.

Thus, the firm's owner chooses PCF such as to solve:

$$\begin{aligned} \text{Max}(SU) = & \text{SID}(EO, FM) \cdot PP(PCF) + \alpha \\ & \cdot (NPV_\alpha - Q(PCF) \cdot PSANC(PCF) \cdot Fine) \end{aligned}$$

The first order condition for Max (SU) is:

$$\frac{\partial SU}{\partial PCF} = \text{SID}(EO, FM) \cdot \frac{\partial PP(PCF)}{\partial PCF} - \alpha \cdot \frac{\partial(Q(PCF) \cdot PSANC(PCF))}{\partial PCF} \cdot Fine = 0$$

So, F.O.C implies:

$$\text{SID}(EO, FM) \cdot \frac{\partial PP(PCF)}{\partial PCF} = \alpha \cdot \frac{\partial(Q(PCF) \cdot PSANC(PCF))}{\partial PCF} \cdot Fine$$

Yielding PCF*, as the optimal (from the viewpoint of the firm's owner) cashflow forecast level.

Note that $\text{SID}(EO, FM), \alpha, Fine > 0$. Further, recall that:

$$\frac{\partial^2 PP}{\partial PCF^2} < 0; \quad \frac{\partial^2(Q(PCF) \cdot PSANC(PCF))}{\partial PCF^2} > 0$$

Thus, we derive the following comparative statics, that may be implemented as testable hypotheses:

$$H(i): \frac{\partial PCF^*}{\partial Fine} < 0;$$

$$H(ii): \frac{\partial PCF^*}{\partial EO} > 0;$$

$$H(iii): \frac{\partial PCF^*}{\partial FM} > 0;$$

$$H(iv): \frac{\partial PCF^*}{\partial \alpha} < 0.$$

5. Data and Descriptive Statistics

We collected mandatory management projected cash flows that were included in annual financial statements, commencing in 2010 and concluding in 2018 (in order to have the

realization of forecasts for 2017).¹³ Utilizing a web scraping tool, together with a manual search of financial statements, we identified 384 firm-year observations of cash flow forecasts that belong to 143 distinct firms.¹⁴ We complemented the manually collected forecasts with consequent-year cash-flow realizations, which were collected manually from the firms' solo financial statements. To measure the level of optimism in management forecasts, we constructed two variables. The first variable, which we call I Am The Firm (ITF), measures the difference between the firm's projected- and realized-cash flow, normalized by the absolute value of the projected cash flow. Higher ITF represents an increased belief by management with regard to cash flow forecasts. To deal with extreme observations, we winsorize ITF at 2.5% and 97.5% of its distribution. As indicated in Table 1, the average (median) ITF in our sample is 0.08 (0.5), i.e., the firms in our sample forecasted cash flows that were, on average, 8% higher than their realized cash flows. The large difference between the mean and the median indicates that our measure of ITF is skewed to the left. Therefore, and in order to alleviate the concern that extreme observations may improperly tilt our results, we introduce a second variable, which we call ITF_DUM, a dummy variable that equals 1 if ITF is positive and zero otherwise. Table 1 indicates that 72% of our firm-year observations predicted ex-post optimistic cash flows. We then proceeded to combine our I Am The Firm measures with financial data available from the Super-Analyst Database.¹⁵ As set forth in Table 1, the average firm size, measured as the natural log of total assets, is 13.42, translated into \$185 Million.¹⁶ LEV is the leverage ratio, measured as total liability scaled by total assets; the mean (median) leverage of our

¹³ Although the law was promulgated in 2008, we excluded years 2008-2009 since initially there was a lack of clarity as to the precise nature of the disclosure requirement; in 2010, ISA published a "clarification guidance" that set forth a coherent unified disclosure of cash flow forecasts.

¹⁴ Firms that were in financial distress were not easily identifiable since ISA requires distress signs to be checked in both the consolidated financial statement and the solo financial statements of firms, but databases of financial statements include only consolidated data. In order to overcome the concern that we would not identify all firms with cash flow forecasts, we employed a web scraping tool and extracted all the annual financial statements from the Tel-Aviv stock exchange website (MAYA.TASE.CO.IL). Through this process, we downloaded 4430 annual files. With the downloaded financial statements in hand, we now had the capacity to perform textual searches to identify firms that disclosed cash flow forecasts. We then searched for "cash flow forecasts" and related phrases in all the downloaded files; this search result yielded 1299 financial statements that were suspected to have cash flow forecasts. We manually opened each file in further pursuit of the collection of the disclosure of cash flow forecasts. After eliminating 759 observations that did not include cash flow forecasts, and an additional 156 observations with missing data, we identified 384 annual observations of cash flow forecasts that belong to 143 distinct firms.

¹⁵ Super-Analyst Database is the source of information reported in financial statements filed with ISA.

¹⁶ The actual value is NIS 667M, which is the equivalent of \$185M on the basis of the 2017 average exchange rate.

firm-year observation is 1.14 (0.85), indicating the intense level of debt overhang of the firms in our data. The average profitability, measured by ROA [return on assets], is negative, consistent with the fact that the companies in our sample were confronting financial difficulties.

Israeli firms are legally required to disclose family relationship among directors and officers in their annual financial statements. We manually collected such data from the annual financial statements of the companies, and coded an eponymous firm indicator, EO, receiving the value 1 if the firm carries the name of family members that serve either on the board of directors or as high-level executive officers and 0 otherwise. 13% of the firm-year observations in our sample carry the family name, which is consistent with prior research findings by Belenzon et al. (2017) (where 19% of European firms in the Amadeus database were eponymous firms). Following Abudy and Shust (2019), we also collected the number of family members serving on boards of directors or as executives and constructed a dummy variable, FM_2, that equals 1 if two or more family members serve the company in such a fiduciary capacity. We gleaned that 45% of firm-year observations in our sample have at least two family members serving as directors or executives. FM_A counts the number of family members who carry active roles in the company as top-level executives (i.e., CEO/CFO) or chairperson of the board. FM_A ranges between 0 to 3. We further collected the percentage of shares held by the largest block-holder, as indicated by LBH. LBH indicates that large block holders hold, on average, 71% of firm's aggregate outstanding shares of the company. A maximum LBH of 1 indicates that for some firms in our data 100% of their shares are held by one block-holder, and bonds are the only financial instrument of these companies that is available to the public. We denote by EXPR the number of years that the firm is disclosing cash flow forecasts, and indicate by DISC_DEV whether the firm's prior cash flow forecast deviated ex-post from its realized cash flows. ISA requires such a disclosure when the deviation is significant, and nearly 40% of our firm-year observations disclosed this deviation. As to industry affiliation, 50% of our firm-year observations belong to the real-estate industry, 22% belong to the holding and investment industry and the remainder is dispersed among various other industries.

[Insert Table 1 Here]

Panel A of Table 2 compares the characteristics of eponymous and non-eponymous firms. Consistent with Belenzon et al. (2017), we observe that eponymous firms are somewhat more profitable than non-eponymous firms, as indicated by the mean difference in ROA of 0.074 (t-stat 1.82). We do not observe other significant differences between eponymous vs. non-eponymous firms in our sample with regard to size of firms, leverage, number of years providing the cash-flow forecasts (EXPR) or in disclosing material deviation in forecasts (DISC_DEV). Panel B of Table 2 compares family firms vs. non-family firms. Following the literature (e.g., Anderson and Reeb, 2003; Villalonga and Amit, 2006; Weiss, 2014; Abudy and Shust, 2019), we define family firms as such in the event that such companies have at least 2 family members serving on the board of directors or as top-tier executives, i.e., FM_2 equals one. We find that family firm-year observations in our sample manifest significantly larger firm size than the non-family firm-year observations, with a difference in mean of 0.709 (t-stat 3.62); family firm-year observations are less leveraged relative to non-family firms, with a difference in mean of -0.424 (t-stat -2.99); yet, the family firm observations have a marginally higher average ROA than their non-family firm counterparts.

[Insert Table 2 Here]

6. Empirical Findings

In our research design, we utilize both univariate and multivariate analysis to examine our hypothesis that the "I Am The Firm" effect taints forecast predictions, prejudicing these prognostications to be overly optimistic in firms with greater personal self-identification, as predicted by our analytical model.

6.1 Univariate Analysis Results

We begin by comparing univariate differences in our I Am The Firm (ITF) variables of interest between eponymous versus non-eponymous firms. Table 3 indicates that ITF in eponymous firms (mean of 0.65) is significantly higher ($p < 0.001$) than in non-eponymous firms (mean of -0.003). Table 3 also indicates that the proportion of firms

with positive ITF, as indicated by ITF_DUM, is significantly higher ($p < 0.001$) in eponymous firms relative to non-eponymous firms: 90% of cash-flow forecasts in eponymous firms were greater than realized cash flows, whereas only 69% of cash-flow forecasts in non-eponymous firms were greater than realized cash flows. These revelatory discrepancies suggest that upward-biased forecasts in eponymous firms are not random.

[Insert Table 3 Here]

6.2 Biased Forecasts are Costly

As discussed in Section 3 above, our research design choice includes the examination of a unique mandatory disclosure requirement of cash flow forecasts at financially distressed firms, together with bifurcating our sample into eponymous and non-eponymous firms. This mandatory disclosure requirement enables us to isolate rational incentives from behavioral tendencies to bias forecasts since the distinctive features and enforcement mechanisms of the disclosure requirement make the skewing of forecasts more expensive. First, the cash-flow forecasts are disclosed mandatorily (not voluntarily as is common worldwide), thus eliminating the inherent self-selection bias of firms in choosing whether or not to disclose forecasts, which characterizes the voluntary disclosure regime. Furthermore, in our setting, the cash-flow forecasts are being vigorously enforced by the regulator both ex-ante, by providing detailed guidance for the form and content of the forecasts' disclosures, and ex-post by rigorously penalizing firms that failed to adequately provide disclosures. Such penalties do not characterize voluntary disclosures – in fact, the SEC, as well as other regulatory bodies, encourage firms to provide forecasts voluntarily and afford them with safe harbor protection (Bozanic, Dietrich and Johnson, 2017). Moreover, cash flow forecasts in financially distressed firms provide essential information that expose the severity of firms' financial condition. Such forecasts are indeed the quintessential opposite of routine decision making, requiring discussion and approval by the board of directors. Finally, we provide evidence that the market itself penalizes firms that disclose biased forecasts.

We claim that the cost of providing biased forecasts intensifies in companies where the concern of its reputation is at stake, as is characteristic of eponymous firms (Belenzon et al., 2017). To support this assertion, we empirically test the market reaction to firms' biased forecasts, conditioning our analysis upon such firms' earnings surprises. We perform an event study approach¹⁷, whereby we examine the cumulative average bond return (CABR(-5+5))¹⁸ with respect to an 11-day window immediately preceding and following the financial statements' filing date (with "zero" as the filing date), while classifying our data into companies with positive vs. non-positive ITF, and separately for eponymous and non-eponymous firms. We hypothesize that firms with positive ITF, i.e., forecasts that were unduly optimistic, predicting substantially higher numbers than the realized outcome, *ceteris paribus*, will be penalized by the market, relative to firms with negative ITF, and such outcomes are intensified in eponymous firms relative to non-eponymous firms. Since cash flow forecasts are disclosed together with the annual financial statement filings, we examine the market response while conditioning on the earnings news conveyed in such filings. As demonstrated in Figure 1, conditioned on firms reporting "good news" (defined as a positive change in earnings, in the current year relative to the prior year),¹⁹ we observe that the average market response (i.e., CABR(-5+5)) of eponymous firms reporting positive ITF is significantly lower than eponymous firms reporting non-positive ITF (with a difference of -2.25% in CABR(-5+5) between the groups and t-stat of 6.68), and is also significantly lower than non-eponymous firms reporting positive ITF (with a difference of -0.73% in CABR(-5+5) between the groups and t-stat of 2.32). Thus, it is apparent that eponymous firms are "punished" by the market for disclosing upward biased forecasts (i.e., positive ITF) more severely than non-eponymous firms or other eponymous firms disclosing more conservative cash-flow forecasts. Yet, even though eponymous firms would be better

¹⁷ For a comprehensive review of the event study approach, see Kliger and Gurevich (2014).

¹⁸ We use bond returns rather than stock returns since some of the firms in our data are privately owned and have only their bonds traded in the Tel Aviv Stock Exchange. Moreover, corporate bonds in Israel are traded on a centralized exchange, offering relatively high liquidity, low spreads and low trading costs. Additionally, our data is comprised of financially distressed firms, and the literature suggests that when a firm is susceptible to default, bond holders become more sensitive to changes in asset value and tend to act more like equity holders (see, for example, Lok and Richardson, 2011). For each firm-year observation, we use one representative bond (in cases where firms have more than one series of bonds). The representative bond was selected by picking the bond with the highest average volume during the 30 days prior to the event window [(-10-39)].

¹⁹ Since we do not have sufficient data with respect to eponymous firms reporting bad news, we concentrate on the market response of firms reporting good news.

off disclosing more conservative forecasts, it appears that there is an underlying behavioral explanation for this phenomenon.

[Insert Figure 1 Here]

We further examine a two-dimensional earnings response model, where our dependent variable is CBR(-5+5) - the cumulative bond return with respect to an 11-day window immediately preceding and following the financial statements' filing date. Our independent variable of interest is the interaction between EO and ITF. We control for earnings news by adding CH_EARN, which is the change in earnings in the current year relative to the prior year, deflated by total assets. We also include year fixed effect, and cluster our standard error at the firm level. Results reported in Appendix B indicate that the coefficient on the interaction term EO*ITF is positive and significant, suggesting that an increase of one percent in ITF by eponymous firms decreases the 11-day cumulative bond return by about 2%. Our results remain qualitatively similar when we extend the cumulative bond return to a 19-day window immediately preceding and following the financial statement filing date, as reported in column 3 and 4 of Appendix B. Overall, the results of this sub-section support our first hypothesis (H(i)), per our analytical model in Section 4), which predicts that the market penalizes firms that disclose biased forecasts.

6.3 I Am The Firm Effect and Eponymous Firms

We proceed to examine hypotheses H(ii) and H(iii) of our analytical model. According to H(ii), the self-identification of the controlling owner in its firm is larger in case of eponymous (EO) ownership, and therefore projected cash flows are predicted to be positively related to EO. We test this hypothesis by examining whether, *ceteris paribus*, eponymous firms are associated with significantly more optimistic mandatory cash flow forecasts, referred to as ITF. More specifically, we test the following regression equations:

Eq. 1.

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_3 SIZE_{it} + \beta_2 ROA_{it} + \beta_4 LEV_{it} + \varepsilon_{it}$$

Eq. 2.

$$Logit(ITF_DUM_{it}) = f[\beta_0 + \beta_1 EO_{it} + \beta_3 SIZE_{it} + \beta_2 ROA_{it} + \beta_4 LEV_{it}] + \varepsilon_{it}$$

In Equation 1, we estimate a pooled cross-sectional linear regression where the dependent variable is a continuous variable that measures the percentage difference between projected cash flows to realized cash flows of firm i at year t . Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. Our independent variable of interest is EO - an eponymous measure that receives the value one in the event that the firm name and family name coincide, and gets zero otherwise. We control for firm SIZE; profitability level measured by ROA; and the capital structure measured by LEV. We also include year and industry fixed effects to control for potential unobserved heterogeneity in years and industries, and cluster the standard errors by firm to eliminate autocorrelation and heteroscedasticity.

In Equation 2, we model the likelihood of estimating optimistic forecasts as a function of EO. Therefore, our independent binary variable ITF_DUM receives the value 1 if ITF is positive, and it gets zero otherwise. All other explanatory variables and controls, including fixed effects and clustering are similar to Eq.1. The results for these two specifications are reported in Columns 1 and 4 of Table 4, which demonstrate that the coefficient on EO is significantly positive and economically large. In Column 1, eponymous firms disclose 65.7 percentage point greater ITF - upwardly biased forecasts (with t-stat of 4.79). To understand the economic significance of self-firm effect, we compare the increase within the ITF distribution. For example, an EO firm moves upward the ITF in the distribution from the 38th percentile to the 75th percentile, which constitutes more than a full quartile of ITF distribution. In Column 4, we report the odd ratio of the logit regression (Eq. 2), and find consistently that the likelihood of eponymous firms predicting optimistic forecasts is more than 3 times larger than of non-eponymous firms making such predictions (with t-stat of 2.08).

[Insert Table 4 Here]

We further examine H(iii), which predicts positive relation between projected cash flows to family firms (FM) through greater self-identification of the controlling family in its firm. We test this hypothesis by examining Eq. 1 and Eq. 2 while substituting eponymous firm (EO) with a common measure of family firm, using FM_2 – a binary variable that receives 1 if there are at least two family members that serve on the board

of directors or as executive officers in firm i at time t , and gets zero otherwise. Column 2 of Table 4 indicates that family firms are associated with significant self-firm effect forecasts, though the magnitude of such forecasts is almost half the magnitude in eponymous firms. The coefficient on FM_2 is 0.3 (t-stat of 2.15); meaning that, ceteris paribus, on average, family firms' self-firm effect level is 30 percentage point greater than the level of non-family firms. Moreover, the logistic regression results reported in Column 5 of Table 4 indicate that the likelihood that family firms will predict optimistic forecasts is 1.7 times larger than non-family firms making such forecasts (with t-stat of 2). In Columns 3 and 6 of Table 4, we include both EO and FM_2 as independent variables, and find that the primary effect holds above and beyond the family firm effect. Overall, the results thus far are consistent with our analytical model prediction, indicating that family firms in general, and eponymous firms in particular, are significantly more prone to adapting self-firm effect bias.

6.4 The Owners' Share of the Firm

We further examine hypothesis (iv), which predicts a negative relation between projected cash flows and the owners' share in the firm (denoted as α in the model). According to our analytical analysis, the owner's share in the firm is negatively associated with greater unrealistic forecasts since such forecasts increase the likelihood of being penalized, which will deteriorate the firms' value. This hypothesis is consistent with the literature suggesting that families with a greater stake of their firms are more incentivized to preserve the family reputation (Bennedsen et al., 2007) and to report more conservative financial statements (Chen et al., 2014). We therefore add an additional explanatory variable of LBH [largest block-holder] to Eq. 1 and Eq. 2, and estimate the following regressions in Table 5:

Eq. 3

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 LBH_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}$$

Eq. 4

$$Logit(ITF_{it}) = f[\beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 LBH_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it}] + \varepsilon_{it}$$

LBH measures the number of shares held by the largest block-holder relative to the aggregate outstanding shares of the firm. The results reported in Table 5 demonstrate that the coefficient on LBH is not consistently negative and is not significantly different than zero. Thus, the stake of the largest stockholder in the firm does not consistently indicate either negative or positive relation to optimistic forecasts. It is important to note that the Israeli market is characterized by concentrated ownership among *all* firms (and not just eponymous or family firms) as is evident in Panel A of Table 2: the average and median percentage of shares in the general market held by the largest block holders is above 70%, which could explain the fact that we do not find the stakeholders among family/eponymous firms, in particular, that are associated with optimistic forecasts.

[Insert Table 5 Here]

6.5 Prior Deviation in Cash Flow Forecasts

In this Section, we examine whether optimistic forecasts are a function of prior deviation in cash flow forecasts as well as the experience of the firm in disclosing such forecasts. We hypothesize that prior deviation in forecasts and the experience of the firm in providing forecasts will be negatively associated with wishful thinking/optimistic forecasts in the current period. Moreover, if rational explanation plays a substantive role in our set-up, then we would expect to see a decline in the magnitude of EO when including prior deviation in cash flow forecasts or the experience of the firm in disclosing such forecasts. We therefore introduce two explanatory variables: DISC_DEV – a binary variable that receives the value one in the event that the firm disclosed that prior forecasts deviated significantly relative to the realized cash flows; and EXPR – a variable that counts the number of years that the firm has been disclosing cash flow forecasts. We estimate the following two regression equations:

Eq. 5:

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 DISC_DEV_{it} + \beta_3 EXPR_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}$$

Eq. 6:

$$\begin{aligned}
& \text{Logit}(ITF_DUM_{it}) \\
& = f[\beta_0 + \beta_1 EO_{it} + \beta_2 DISC_DEV_{it} + \beta_3 EXPR_{it} + \beta_4 SIZE_{it} \\
& \quad + \beta_5 ROA_{it} + \beta_6 LEV_{it}] + \varepsilon_{it}
\end{aligned}$$

Results reported in Table 6 indicate that EXPR and DISC_DEV are indeed negatively associated with optimistic forecasts, yet not in a significant manner. Consistent with our primary hypothesis that self-firm effect bias is driving our results, we observe in Table 6 that the magnitude level of EO and its significant level remains similar to those reported in Table 4.

[Insert Table 6 Here]

6.6 Active Family Members

The literature suggests that the level of involvement of the family in active roles in the firm has a substantial effect upon the behavior of family firms (see, e.g., Anderson and Reeb, 2003; Maury, 2006; Abudy and Shust, 2019). However, in eponymous firms, self-firm effect is not necessarily affected by active family members since the reputation concern that is at stake plays a role in the involvement of the family without regard to the official roles held by the family in the firm. More specifically, we test the following regression equation:

Eq. 7:

$$\begin{aligned}
ITF_{it} = & \beta_0 + \beta_1 EO_{it} + \beta_2 FM_A_{it} + \beta_3 EO_{it} * FM_ACTIVE_{it} + \beta_4 SIZE_{it} \\
& + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}
\end{aligned}$$

FM_A measures the number of active, top roles in the firm (i.e., as high-level executives (CEO, CFO) or as the chairperson of the board) that are being held by a family member at year t.

In Table 7, we report the result, showing that EO is positive and significant whereas the interaction of EO with FM_A is not different than zero, indicating that self-firm effect

characterizes eponymous firms without regard to the actual active roles held by the family.

[Insert Table 7 Here]

7 Concluding Remarks

In this paper, we examine the hypothesis that in certain firms, there is a blurring of the boundaries between the firm and the persons who control and lead the firm, which profoundly affects corporate forecast disclosures. We define this self-serving bias as an "I Am The Firm" effect, which is an allegorical reference to the famous declaration articulated by Louis XIV (1638-1715): "l'État, c'est moi" – "I am the State." Our research is facilitated by a unique set-up in Israel, where the Securities Authority mandates the disclosure of cash flow forecasts with regard to specific financially distressed firms. We find that eponymous firms, i.e., firms that carry the names of their controlling owners, who naturally have greater personal attachment to their firms, disclose significantly more optimistic cash flow forecasts – at a rate three times greater – than their non-eponymous counterparts. We demonstrate that these results do not appear to be explicated by rational incentives, such as reputation concern or the incurrence costs associated with providing optimistic forecasts in our setting. Overall, our results support our hypothesis that such firms are suffused with a self-serving "I Am The Firm" bias that obfuscates the boundaries between the subjective illusory desires of the eponymous personnel and the objective realistic truths of the firm's actual financial state.

The "I am the Firm" (or "ITF") effect has extensive implications on various aspects related to corporate decision making that should be studied in future research. One example of such potential future research is to investigate the range of differences in the premiums offered by controlling families of eponymous firms to buy out the stake of minority shareholders in the process of delisting such firms and taking them private. Utilizing data from Hamdani et al. (2020), we find evidence that premiums offered in eponymous firms may be lower than those offered in non-eponymous firms. We believe that a possible explanation for lower premiums in eponymous firms is the "I Am The Firm" effect. The ITF owner or executive may insist – consciously or

unconsciously – that since "I am the Firm," I will not pay a high premium to minority shareholders for delisting "my" firm. Moreover, the ITF effect can be applied not only with respect to eponymous (or family) firms, as we have done here, but also to other set-ups where executive decision-makers are personally identified with their companies

After a 72-year reign, on his deathbed, Louis XIV qualified his youthful, narcissistic claim of "l'État, c'est moi." As he stated, "Je m'en vais, mais l'État demeurera toujours" – "I depart, but the State shall always remain." For an eponymous company to survive, it would be prudent for its shareholders and executives to take heed.

Figure 1:

Bond Response to Biased Forecasts in Eponymous Vs. Non-Eponymous Firms Conditioning on Firms Reporting "Good News"

Figure 1 plots the cumulative average bond return (CABR) at a window of 11 days immediately preceding and following the financial statements filing date (i.e., -5 +5 days around the filing; day 0 is the filing date). We calculate CABR for firms that reported optimistic forecasts (i.e. ITF_DUM equals one) vs. pessimistic forecasts (i.e. ITF_DUM equals zero), separately for eponymous and non-eponymous firms, conditioning that firms reported good news. The blue line is the CABR of eponymous firms that reported optimistic forecasts (denoted as GOOD_EO_OPTIM); the green line is the CABR of non-eponymous firms that reported optimistic forecasts (denoted as GOOD_NEO_OPTIM); the red line is the CABR of eponymous firms that reported pessimistic forecasts (denoted as GOOD_EO_PESIM); the orange line is the CABR of non-eponymous firms that reported pessimistic forecasts (denoted as GOOD_NEO_PESIM). Optimistic/pessimistic forecasts are classified according to ITF_DUM; if ITF_DUM is 1(0), we refer to it as optimistic (pessimistic) forecasts. ITF_DUM gets 1(0) if ITF is positive (negative). Good news is classified according to the change in earnings in the current year relative to the prior year. A positive change in earnings indicates good news. EO indicates whether it is an eponymous firm; EO gets 1 if the firm carries the name of the family members that serve on the board of directors or as executives.

ITF_DUM	90%	> (sig < 0.01)	69%

Panel B - Within Family Firms

	EO		Non-EO
ITF	0.670	> (sig<0.01)	0.142
ITF_DUM	90%	> (sig<0.05)	76%

This table describes the mean differences in our variables of interest between eponymous and non-eponymous firms. The first row describes the differences in ITF measured as the difference between projected cash flows to realized cash flows, relative to the absolute value of the projected cash flows. Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. The second row describes the differences in the binary variable ITF_DUM that measures the proportion of firms with positive ITF. EO is a binary variable that gets one for eponymous firms i.e., firms that carry the name of the family members that serve on the board of directors or as executives, and gets zero otherwise.

Table 4 – I Am The Firm and Eponymous Firm

	<i>ITF</i> <i>(OLS)</i>			<i>ITF_DUM</i> <i>(Logit)</i>		
	1	2	3	4	5	6
EO	0.657*** (4.79)		0.579*** (3.88)	3.296** (2.08)		2.847* (1.78)
FM_2		0.300** (2.15)	0.193 (1.32)		1.7** (2.0)	1.485 (1.47)
SIZE	0.014 (0.38)	-0.003 (-0.08)	0.007 (0.19)	1.046 (0.6)	1.021 (0.27)	1.034 (0.45)
ROA	0.460** (2.47)	0.501*** (2.64)	0.457** (2.45)	3.414* (1.86)	3.517* (1.95)	3.343* (1.88)
LEV	0.01 (0.2)	0.009 (0.17)	0.0125 (0.24)	0.966 (-0.38)	0.958 (-0.50)	0.968 (-0.35)
Intercept	0.101 (0.18)	0.277 (0.49)	0.135 (0.25)	2.814 (0.86)	1.508 (1.04)	2.965 (0.93)
Year FE	Yes	Yes	Yes	Yes	Yes	Yes
Ind FE	Yes	Yes	Yes	Yes	Yes	Yes
Firm Clustering	Yes	Yes	Yes	Yes	Yes	Yes
Observations	384	384	384	384	384	384
Adj R ² / Pseudo R ²	0.04	0.024	0.042	0.082	0.076	0.087

Notes: In this table, columns 1, 2 and 3 report the estimation results of Eq. 1:

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 SIZE_{it} + \beta_4 ROA_{it} + \beta_5 LEV_{it} + \varepsilon_{it}$$

Columns 4, 5 and 6 report the estimation results of Eq. 2:

$$Logit(ITF_DUM_{it}) = f[\beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 SIZE_{it} + \beta_4 ROA_{it} + \beta_5 LEV_{it}] + \varepsilon_{it}$$

The dependent variable in columns 1, 2 and 3 is ITF measured as the difference between projected cash flows to realized cash flows, relative to the absolute value of the projected cash flows. Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. The dependent variable in columns 4, 5 and 6 is ITF_DUM, a binary variable that measures the proportion of firms with positive ITF. Our primary independent variable, EO, is reported in columns 1 and 4; EO gets 1 if the firm carries the family name of the family members serving as directors or executives of the firm, and 0 otherwise. In columns 2 and 5, we substitute EO with FM_2, a binary variable that gets the value 1 if the firm has at least 2 family members serving as directors or executives. Columns 3 and 6 include both EO and FM_2. All regressions include year and industry fixed effects. T-stat clustered by firms are reported in parentheses. In columns 4-6, we report the odds-ratios instead of the coefficients. ***, **, and * indicate a significance level of 0.01, 0.05, and 0.10, respectively.

Table 5 – I Am The Firm Controlling for the Numbers of Shares Held by the Largest Block Holder

	<i>ITF</i> (<i>OLS</i>)			<i>ITF_DUM</i> (<i>Logit</i>)		
	1	2	3	4	5	6

ROA	0.459** (2.46)	0.504*** (2.65)	0.454** (2.43)	3.504* (1.95)	3.589** (2.05)	3.412* (1.96)
LEV	0.00929 (0.19)	0.0102 (0.2)	0.012 (0.22)	0.974 (-0.28)	0.969 (-0.35)	0.976 (-0.26)
Intercept	0.123 (0.22)	0.225 (0.41)	0.17 (0.31)	1.914 (0.53)	2.14 (0.62)	2.027 (0.59)
Year FE	Yes	Yes	Yes	Yes	Yes	Yes
Ind FE	Yes	Yes	Yes	Yes	Yes	Yes
Firm						
Clustering	Yes	Yes	Yes	Yes	Yes	Yes
Observations	384	384	384	384	384	384
Adj R ² / Pseudo R ²	0.037	0.022	0.039	0.085	0.081	0.091

Notes: In this table, columns 1, 2 and 3 report the estimation results of Eq. 3:

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 LBH_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}$$

Columns 4, 5 and 6 report the estimation results of Eq. 4:

$$Logit(ITF_DUM_{it}) = f[\beta_0 + \beta_1 EO_{it} + \beta_2 FM_2_{it} + \beta_3 LBH_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it}] + \varepsilon_{it}$$

In Eqs.3 and 4 (relative to Eqs. 1 and 2), we add LBH as an explanatory variable. LBH measures the number of shares held by the largest block-holder relative to the outstanding shares in the firm. The dependent variable in columns 1, 2 and 3 is ITF measured as the difference between projected cash flows to realized cash flows, relative to the absolute value of the projected cash flows. Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. The dependent variable in columns 4, 5 and 6 is ITF_DUM, a binary variable that measures the proportion of firms with positive ITF. EO is reported in columns 1 and 4; EO gets 1 if the firm carries the family name of the family members serving as directors or executives of the firm, and 0 otherwise. In columns 2 and 5, we substitute EO with FM_2, a binary variable that receives the value 1 if the firm has at least 2 family members serving as directors or executives. Columns 3 and 6 include both EO and FM_2. All regressions include year and industry fixed effects. T-stat clustered by firms are reported in parentheses. In columns 4-6, we report the odds-ratios instead of the coefficients. ***, **, and * indicate a significance level of 0.01, 0.05, and 0.10, respectively.

Table 6 – I Am The Firm Controlling for Prior Deviation in CF Forecasts

SIZE	0.009 (0.25)	-0.010 (-0.25)	0.001 (0.04)	1.060 (0.77)	1.024 (0.31)	1.042 (0.55)
ROA	0.431** (2.24)	0.476** (2.46)	0.420** (2.17)	3.158* (1.75)	3.310* (1.86)	3.058* (1.74)
LEV	0.005 (0.11)	0.005 (0.1)	0.010 (0.21)	0.983 (-0.18)	0.974 (-0.29)	0.988 (-0.13)
Constant	0.347 (0.74)	0.525 (1.09)	0.369 (0.8)	2.468 (0.83)	3.422 (1.12)	2.645 (0.91)
Year FE	Yes	Yes	Yes	Yes	Yes	Yes
Firm Clustering	Yes	Yes	Yes	Yes	Yes	Yes
Observations	384	384	384	384	384	384
Adj R ² / Pseudo R ²						
	0.03	0.015	0.033	0.057	0.051	0.064

Notes: In this table, columns 1, 2 and 3 report the estimation results of Eq. 5:

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 DISC_DEV_{it} + \beta_3 EXPR_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}$$

Columns 4, 5 and 6 report the estimation results of Eq. 6:

$$\begin{aligned} &Logit(ITF_DUM_{it}) \\ &= f[\beta_0 + \beta_1 EO_{it} + \beta_2 DISC_DEV_{it} + \beta_3 EXPR_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} \\ &+ \beta_6 LEV_{it}] + \varepsilon_{it} \end{aligned}$$

In Eqs. 5 and 6 (relative to Eqs. 1 and 2), we add DISC_DEV and EXPR as explanatory variables. DISC_DEV receives the value 1 if the firm disclosed at time t that the realization of cash flow forecasts deviated significantly from the predicted cash flows, as disclosed at t-1, and receives 0 otherwise. EXP counts the number of years that the firm is disclosing cash flow forecasts, i.e., its experience in forecasting cash flows. If it is the first time that the firm is disclosing the forecasts, EXPR will receive the value 1, and so forth. The dependent variable in columns 1, 2 and 3 is ITF measured as the difference between projected cash flows to realized cash flows, relative to the absolute value of the projected cash flows. Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. The dependent variable in columns 4, 5 and 6 is ITF_DUM, a binary variable that measures the proportion of firms with positive ITF. EO is reported in columns 1 and 4; EO gets 1 if the firm carries the family name of the family members serving as directors or executives of the firm, and 0 otherwise. In columns 2 and 5, we substitute EO with FM_2, a binary variable that receives the value 1 if the firm has at least 2 family members serving as directors or executives. Columns 3 and 6 include both EO and FM_2. All regressions include year and industry fixed effects. T-stat clustered by firms are reported in parentheses. In columns 4-6, we report the odds-ratios instead of the coefficients. ***, **, and * indicate a significance level of 0.01, 0.05, and 0.10, respectively.

Table 7 - I Am The Firm and Active Family Members

	<i>ITF</i>	<i>ITF</i>
	(1)	(2)
EO	0.570*** (2.70)	0.670*** (3.13)
FM_ACTIVE	0.173* (1.85)

Constant	0.0679 (0.12)	0.0994 (0.18)
Observations	384	384
Adj R²	0.042	0.037

Notes: The table reports the estimation results of Eq. 7:

$$ITF_{it} = \beta_0 + \beta_1 EO_{it} + \beta_2 FM_ACTIVE_{it} + \beta_3 EO_{it} * FM_ACTIVE_{it} + \beta_4 SIZE_{it} + \beta_5 ROA_{it} + \beta_6 LEV_{it} + \varepsilon_{it}$$

The dependent variable ITF is measured as the difference between projected cash flows to realized cash flows, relative to the absolute value of the projected cash flows. Higher rates of ITF represent increased sentiment of self-serving belief by management with regard to cash flow forecasts. Our primary independent variables are: EO – eponymous firm indicator; FM_ACTIVE - a continuous variable that counts the number of active, top-tier roles (i.e., leading executives (CEO, CFO) or the chairperson of the board) held by family members, at year t; and the interaction between EO and FM_ACTIVE. In column 2, we replace FM_ACTIVE with FM_ACTIVE_DUMM - a binary variable that gets 1 if FM_ACTIVE is greater than 1, and gets 0 otherwise. We also include in column 2 the interaction of EO with FM_ACTIVE_DUMM. All regressions include year and industry fixed effects. T-stat clustered by firms are reported in parentheses. ***, **, and * indicate a significance level of 0.01, 0.05, and 0.10, respectively.

Appendix A: Variables Definition

Variable Name	Description
$ITF_{i,t}$	<p>The difference between firm i's projected cash flows at time $t+1$ and realized cash flows for time $t+1$, disclosed at time t, deflated by the absolute value of the projected cash flow.</p> $ITF_{i,t} = \frac{PROJECTED_CF_{i,t} - REALIZED_CF_{i,t}}{ PROJECTED_CF_{i,t} }$
$ITF_DUM_{i,t}$	Receives the value 1 if $ITF_{i,t}$ is positive, and 0 otherwise.
$EO_{i,t}$	Receives the value 1 if the firm carries the family name of the controlling family, and 0 otherwise.
$FM_2_{i,t}$	Receives the value 1 if the number of family members serving as directors or officers is at least two, and 0 otherwise.
$FM_A_{i,t}$	The number of active, top-tier roles in the firm (i.e., as leading executives (CEO, CFO) or as the chairperson of the board) held by a family member at year t .
LBH	The number of shares held by the largest block-holder relative to the outstanding shares of the firm.
$DISC_DEV_{i,t}$	Receives the value 1 if the firm disclosed at time t that the realization of the cash flow forecast deviated significantly from the predicted cash flows, as disclosed at $t-1$, and 0 otherwise.
EXPR	The number of years that the firm is disclosing cash flow forecasts, i.e. its experience in forecasting cash flows. If it is the first time that the firm is disclosing the forecasts, EXPR receives the value 1, and so forth.
SIZE	Natural log of total assets.
LEV	Total liabilities scaled by total assets.
ROA	Net income scaled by total assets.

Notes: The table reports the cumulative bond return (CBR) immediately preceding and following earnings news and deviation from prior cash-flow forecasts in eponymous vs. non eponymous firms. Columns 1 and 2 report the cumulative bond return at a window of 11 days immediately preceding and following the financial statements filing date (i.e., -5 +5 days around the filing date; day 0 is the filing date). Columns 3 and 4 report the cumulative bond return at a window of 19 days immediately preceding and following the financial statements filing date (i.e., -9 +9 days immediately preceding and following the filing date; day 0 is the filing date). CH_EARN is the change in earnings in the current year relative to the prior year deflated by total assets. ITF_{t-1} is the difference between projected cash flows for time t as reported in time t-1 to realized cash flows, relative to the absolute value of the projected cash flows. EO is an eponymous firm indicator and is the interaction term. T-stat clustered by firms are reported in parentheses. ***, **, and * indicate a significance level of 0.01, 0.05, and 0.10, respectively.
